Modul:Format TemplateData

Vorlage:Nutshell Vorlage:Lua

`TemplateData` – Module with auxilary functions for template documentation, especially by TemplateData.

Core functionality is improved presentation on documentation pages.

Inhaltsverzeichnis

Vorlage:Anchor Improve template documentation page – MediaWiki disappointing

For presentation of template depiction in VisualEditor agreement was made to abandon all markup and clickable links, permitting all tooltips in all environments. Basically this is reasonable, albeit tooltips with markup and clickable links are supported as HTML application for decades now and JavaScript is present anyway when VisualEditor is used.

- In consequence it was decided, that also presentation on template documentation views never ever is permitted to contain effective links or markup.
- That involved, that on many template documentation pages two separated parameter documentation tables are needed and required to be maintained simultaneously: One plain text version for VisualEditor, and a useful one for complex circumstances, with links and markup and lists and tables. – BTW, VisualEditor has not only tooltips, but also a static GUI view, where the lack of deepening links in parameter description is painful.

This state is indefensible.

Vorlage:Anchor Improved presentation

In addition to the simple syntax supported by MediaWiki and presented in the VisualEditor, the following features can be added to the JSON code for the template documentation page. They affect the elements classified as *InterfaceText*, but are only useful for description fields.

Wikilinks (internal format)

- Using double square brackets pages can be linked as common.
- In VisualEditor, only link title is visible, as it is displayed otherwise.

External links (URL format)

- Open URL are linked as usual by themselves. In VisualEditor they appear as normal text.
- External links enclosed in simple square brackets are displayed normally on the template documentation page. In VisualEditor the title is omitted and the URL is displayed so that the users can c&p it and transfer it to the address field of the browser. There is no other way.

Apostrophs `'` for italic and bold

- They can be used to emphasize on the documentation page and are missing in VisualEditor (regular script).

HTML entities

- The following entities can be used: `< > & &quot;  ` and all numeric formats.

HTML tags

- HTML tags (and the MediaWiki elements that are not replaced in advance) are removed for the VisualEditor. Otherwise, they remain effective.
- Attributes are often included in `"`, which conflicts with the JSON syntax. It is important to make sure that `'` is used, which can be a problem with template transclusions.

`<noexport>` ... `</noexport>`

- The enclosed areas are not exported to the VisualEditor.
- More complex wiki syntax and extensive explanations can be restricted to the documentation page.
- Within a *noexport* area, the line structure of the source text is considered. Otherwise everything is running in a single line, as it would also be represented in the VisualEditor.

Templates

- In particular when the template parameter `JSON=` is used, templates can be distributed anywhere in the JSON code. However, the expanded syntax might collide with the JSON syntax.

More effects

- According to the state (required, suggested, optional, deprecated) the table rows are highlighted in light blue, white, gray and pale red.
- When sorting by state, this importance is taken into account and not the alphabetical sequence of the keywords.
- Each parameter can be addressed as a jump destination. The fragment is `#templatedata:` *parameter-name*.
- Missing labels are highlighted as errors.

- A maintenance category is triggered if errors occur.
- If there are no parameters, the element `params:{}` is not required.

Eliminate disadvantages

Two aspects were found to be particularly disturbing in 2013–2017:

1. Even if no parameters at all were defined, a table head is always displayed for a table without content. Even more, this is sortable.
   - A reduction was rejected with Vorlage:Phab. A sortable table of the parameters would be always necessary, even if the table has no rows at all and consists only of the header row.
   - This ridiculous statement led to the development of this module in 2016.
2. Even if the context does not permit that default values or even AutoValue specifications will be defined ever, a content-free six-line definition list is output for each individual parameter value.
   - Vorlage:Phab / Vorlage:Phab / Vorlage:Phab / Vorlage:Phab
   - MediaWiki did not even deign to answer the disastrous documentation page situation.

The general comments show that MediaWiki only regards the presentation of TemplateData specifications in the VisualEditor as important. However, someone has to program and maintain the templates and someone needs to generate the template description and make it manageable beside the functionality in the VisualEditor form, but that is beyond ken.

General workflow

- An attempt is made to read the JSON object (string) from passed template parameters.
- If this failed, the source code of the current and the documentation page is searched for `<templatedata>` elements.
- Two representations are obtained from the JSON object input:
  1. A localized version, markup etc. stripped off, in JSON format.
  2. An HTML structure, basically similar to the MediaWiki representation, possibly with table of the parameters, with enhanced features.
- The result of the template is a visible documentation with markup, followed by a hidden `<templatedata>` element. This is done for the export and corresponds to the MediaWiki guidelines.
  - If current page has been identified as documentation page the hidden `<templatedata>` is suppressed, and those pages do not appear separately in Special:PagesWithProp/templatedata.

Vorlage:Anchor Functions for templates

Details

f Vorlage:Anchor

Improve TemplateData-presentation; used in Template:Format TemplateData

Parameters of template transclusion environment (all optional):

1
: JSON string or `<templatedata>` object

JSON
: JSON string
(precedes **1**)
Transition from `<templatedata>` objects with pipe symbols needs special attention: Pipes are to be represented as `{{!}}`, on double curly brackets one should be encoded by HTML entity.

TOC
: `1` – Insert table of contents after general purpose descriptions; but before parameter list, if present
Example

lazy
: `1` – Presentation only, do not generate an effective data block
For general method descriptions.

debug
: `1` – developer mode

Parameters of `#invoke` *for particular project adaption (all optional):*

cat
: Title of a maintenance category on invalid parameter value etc.

debug
: Development mode, if provided and not equal `0`

docpageCreate
: Pattern for creation of subpage names; `%s/Doku`

docpageDetect
: Pattern for recognition of subpage names; `/Doku$`

msgDescMiss
: Localisation: complaint text on missing `description`

Returns: HTML code; and/or error message, probably with `class="error"`

failsafe **Vorlage:Anchor**
: Version identification: `2017-11-06`
Optional additional parameter `1` – requested minimal version identification
Returns: (empty), if minimal version condition not matched

Examples (test page)

A test page illustrates practical use.

Vorlage:Anchor Functions for Lua modules (API)

Some functions described above can be used by other modules:

```
local lucky, TemplateData = pcall( require, "Module:Format TemplateData" )
if type( TemplateData ) == "table" then
    TemplateData = TemplateData.TemplateData()
else
    -- failure; TemplateData is the error message
    return "<span class='error'>" .. TemplateData .. "</span>"
end
```

TemplateData.failsafe(atleast)

1. atleast
   optional
   nil or minimal version request

Returns: *string* or *false*

TemplateData.getPlainJSON(adapt)

Reduce enhanced JSON information to MediaWiki JSON

1. adapt
   string, with JSON (enhanced)

Returns: *string*, with JSON (MediaWiki)

TemplateData.test(adapt, arglist)

Simulation of template functionality

1. adapt
   table, `#invoke` parameters
2. arglist
   table, template parameters

Returns: *string*

Usage

Currently focusing on one template only:

- Template:Format TemplateData

Dependencies

- Module:Plain text
- Module:TNT (for the Vorlage:Para parameter)

```
local TemplateData = { serial = "2017-11-06",
                       suite  = "TemplateData" }
local plaintext = require("Module:Plain text")
--[=[
improve template:TemplateData
]=]
local Config = {
    -- multiple #invoke option names mapped into unique internal fields
    cat            = "strange",
    classNoNumTOC  = "suppressTOCnum",
```

```
--  classParams    = "classTable",
    cssParams      = "stylesTable",
    cssParWrap     = "stylesTabWrap",
    debug          = false,
    docpageCreate  = "suffix",
    docpageDetect  = "subpage",
    msgDescMiss    = "solo",
--  classTable     = false,    -- class for params table
    loudly         = false,    -- show exported element, etc.
    solo           = false,    -- complaint on missing description
    strange        = false,    -- title of maintenance category
    stylesTable    = false,    -- styles for params table
    stylesTabWrap  = false,    -- styles for params table wrapper
    subpage        = false,    -- pattern to identify subpage
    suffix         = false,     -- subpage creation scheme
    suppressTOCnum = false    -- class for TOC number suppression
}

Modul:Plain text

Developed for producing short descriptions from text that may have markup, or other stuff that needs removing from short descriptions.

Usage

Code

`'''[[foo|hah]]''' <span style="color:red">is</span> '''''[[gah]]'''''<nowiki>?</nowiki>` →

hah is ***gah***?

Using modul

`{{#invoke:Plain text|main|1='''[[foo|hah]]''' <span style="color:red">is</span> '''''[[gah]]'''''<nowiki>?</nowiki>}}` →

Vorlage:Plain text

Modul:TNT

This module allows templates and modules to be easily translated as part of the multilingual templates and modules project. Instead of storing English text in a module or a template, TNT module allows modules to be designed language-neutral, and store multilingual text in the tabular data pages on Commons. This way your module or template will use those translated strings (messages), or if the message has not yet been translated, will fallback to English. When someone updates the translation table, your page will automatically update (might take some time, or you can purge it), but no change in the template or module is needed on any of the wikis. This process is very similar to MediaWiki's localisation, and supports all standard localization conventions such as {{PLURAL|...}} and other parameters.

This module can be used from templates using #invoke, and from other modules. For a simple example, see Data:I18n/Template:Graphs.tab - a table with two messages, each message having a single parameter. By convention, all translation tables should have '''Data:I18n/...''' prefix to separate them from other types of data.

Inhaltsverzeichnis

Using from Templates

Description	Wiki Markup

In a template, this command translates **source_table** message using Commons' Data:I18n/Template:Graphs.tab translation table.	`{{#invoke:TNT | msg`
	`| I18n/Template:Graphs.tab`
	`| source_table`
	`}}`

If your message contains parameters, you can specify them after the message ID.	`{{#invoke:TNT | msg`
	`| I18n/Template:My Template.tab`
	`| message-with-two-params`
	`| param1`
	`| param2`
	`}}`

Translating Template Parameters

Template parameters are usually stored as a JSON **templatedata** block inside the template's /doc subpage. This makes it convenient to translate, but when a new parameter is added to a global template, all /doc pages need to be updated in every language. TNT helps with this by automatically generating the templatedata block from a table stored on Commons. Placing this line into every /doc sub-page will use Data:Templatedata/Graph:Lines.tab table to generate all the needed templatedata information in every language. Even if the local community has not translated the full template documentation, they will be able to see all template parameters, centrally updated.

```
{{#invoke:TNT | doc | Graph:Lines }}
```

Using from Modules

Just like templates, modules should also use this module for localization:

```
local TNT = require('Module:TNT')

-- format <messageId> string with two parameters using a translation table.
local text = TNT.format('I18n/My_module_messages', 'messageId', 'param1', 'param2

-- Same, but translate to a specific language.
local text = TNT.formatInLanguage('fr', 'I18n/My_module_messages', 'messageId',
```

Using TNTTools

Module:TNTTools has:

- Question functions: with boolean or numerical indexed return. To be called from other modules or from templates. With:
  - Case sensitive option.
  - Possibility of more than one translated text value (where each value is separated by "|").
- To put aside write, adding "I18n/" as a prefix and ".tab" extension as a suffix for the table names.
- Several examples.

```
--
-- INTRO:   (!!! DO NOT RENAME THIS PAGE !!!)
--    This module allows any template or module to be copy/pasted between
--    wikis without any translation changes. All translation text is stored
--    in the global  Data:*.tab  pages on Commons, and used everywhere.
--
-- SEE:   https://www.mediawiki.org/wiki/Multilingual_Templates_and_Modules
--
-- ATTENTION:
--    Please do NOT rename this module - it has to be identical on all wikis.
--    This code is maintained at https://www.mediawiki.org/wiki/Module:TNT
```

```
--    Please do not modify it anywhere else, as it may get copied and override yo
--    Suggestions can be made at https://www.mediawiki.org/wiki/Module_talk:TNT
--
-- DESCRIPTION:
--    The "msg" function uses a Commons dataset to translate a message
--    with a given key (e.g. source-table), plus optional arguments
--    to the wiki markup in the current content language.
--    Use lang=xx to set language.  Example:
--
--    {{#invoke:TNT | msg
--     | I18n/Template:Graphs.tab  <!-- https://commons.wikimedia.org/wiki/Data:I
--     | source-table              <!-- uses a translation message with id = "sou
--     | param1 }}                 <!-- optional parameter -->
--
--
--    The "doc" function will generate the <templatedata> parameter documentation
--    This way all template parameters can be stored and localized in a single Co
--    NOTE: "doc" assumes that all documentation is located in Data:Templatedata/
--
--    {{#invoke:TNT | doc | Graph:Lines }}
--        uses https://commons.wikimedia.org/wiki/Data:Templatedata/Graph:Lines.t
--        if the current page is Template:Graph:Lines/doc
--
